Final Project - 2

Faculty of Management - Midocean University

Supervisor

Dr. Mona Moustafa Elashry

Faculty member- Faculty of management- Midocean University

2nd Semester- 2024

Acknowledgment

I extend my deepest gratitude to Dr. Mona Moustafa Elashry for her invaluable guidance and unwavering support throughout the duration of this project. Her expertise and insights have been instrumental in shaping both the direction and success of this research.

I am also thankful to the Midocean University for providing the essential resources and a conducive environment that have greatly facilitated my research activities.

Special thanks are due to all the participants who generously shared their time and experiences, contributing significantly to the richness of the data collected. Their involvement was crucial to the depth and breadth of this analysis.

Additionally, I appreciate the support and encouragement from my family and friends, who provided motivation and a supportive environment during my research journey.

Dedication

This project is lovingly dedicated to my family, whose enduring love and steadfast support have been the cornerstone of my success. To my parents, who have always believed in me even when challenges seemed insurmountable, your sacrifices have not gone unnoticed, and this achievement is as much yours as it is mine. To my siblings, whose humor and companionship have lightened my days, you are my constant reminder that persistence and laughter can overcome the toughest trials.

I dedicate this work to my mentors and teachers, especially Dr. Mona Moustafa Elashry, who guided me with patience and wisdom throughout my research journey. Your dedication to nurturing curious minds has deeply inspired me and shaped my academic path.

To my friends, both near and far, who have provided endless encouragement and necessary distractions along the way, this journey would have been much less joyful without you.

Lastly, this project is dedicated to all adolescents grappling with the challenges of mental health in our increasingly digital world. It is my fervent hope that this study sheds light on the nuanced ways social media impacts our lives and contributes to a broader understanding that sparks meaningful change and support.

May this work serve as a beacon of knowledge and hope, inspiring continued research and advocacy in the field of adolescent mental health.

1. Chapter 1: Introduction

1.1. Research Background

In the digital age, social media platforms have revolutionized communication and become a central part of daily life for adolescents worldwide. These platforms, such as Instagram, Snapchat, and Facebook, offer unprecedented opportunities for social interaction, self-expression, and learning. However, alongside these benefits, the proliferation of social media has raised concerns among researchers, educators, and healthcare professionals regarding its impact on the mental health of young users.

Stage 1: Establishing a Context

Research indicates a significant correlation between increased screen time and lower psychological well-being among adolescents (Twenge & Campbell, 2018). The relationship between digital technology use and adolescent well-being remains complex, with both positive and negative outcomes observed (Orben & Przybylski, 2019). Online communication and social media have both positive and negative impacts on adolescent well-being, as highlighted in various systematic reviews (Best, Manktelow, & Taylor, 2014).

Stage 2: Identifying the Gaps in Existing Research

Depression disclosures on social networking sites like Facebook indicate a strong association between social media use and mental health issues among adolescents (Moreno et al., 2011). The Goldilocks hypothesis suggests that moderate digital-screen use may be beneficial, while too little or too much can be detrimental to adolescent mental well-being (Przybylski & Weinstein, 2017). Viewing others' highlight reels on social media platforms like Facebook is linked to increased depressive symptoms among adolescents (Steers, Wickham, & Acitelli, 2014). Adolescents face various risks, including sexual and aggressive behaviors, due to online and mobile technologies, necessitating a thorough understanding of these digital interactions (Livingstone & Smith, 2014).

Stage 3: Stating the Importance of the Issue

Adolescence is a critical period characterized by intense social and psychological development, making young people particularly vulnerable to the influences of their environments. Social media use has been linked to poor sleep quality and increased levels of anxiety and depression among adolescents (Woods & Scott, 2016). The potential influence of social media on this aspect of youth development cannot be overstated, as highlighted by the significant correlation between increased screen time and lower psychological well-being (Twenge & Campbell, 2018).

Stage 4: Stating the Research Objective

This research aims to dissect the multifaceted relationship between social media usage and adolescent mental health. Specifically, it seeks to understand the psychological mechanisms at play and assess how individual differences, such as personality traits and socio-economic status, influence the relationship between **social** media use and mental health outcomes. By comprehensively analyzing these relationships, this study hopes to contribute robust evidence to the ongoing debate and aid in the formulation of nuanced, evidence-based approaches to manage and harness the power of social media in supporting adolescent development.

Stage 5: Previewing the Structure of the Research

The structure of this research will encompass a mixed-methods approach, employing both quantitative and qualitative research designs to capture a broad spectrum of interactions between social media use and mental health. Initially, a comprehensive literature review will set the stage by summarizing existing research and theories related to the impact of social media on mental health. This will be followed by a detailed explanation of the research methodology, including data collection methods and analytical techniques. Subsequent sections will present the findings, discuss their implications, and explore potential interventions and policies. The final sections will reflect on the limitations of the current study and suggest directions for future research. By incorporating these additional references and structuring the text accordingly, your research background will be well-supported with a diverse range of studies, providing a robust foundation for your research.

1.2. Research Problem

The ubiquitous integration of social media into the lives of adolescents presents both opportunities and challenges that significantly impact their psychological development and well-being. Despite the growing body of research on this subject, critical gaps remain in our theoretical understanding and practical knowledge. Addressing these gaps is essential to comprehensively assess the nuanced effects of social media on adolescent mental health and to guide the development of effective interventions. This section outlines the existing gaps in both theoretical frameworks and practical applications and poses a central research question to guide the study.

1.2.1. Theoretical Gaps

The theoretical landscape surrounding the impact of social media on adolescent mental health is marked by diverse perspectives and incomplete models that often fail to capture the complex interactions between individual characteristics and social media use. One significant gap lies in the insufficient understanding of the psychological mechanisms that mediate the relationship between social media engagement and mental health outcomes. Current theories often do not account for the variability in individual user experiences, including how personal traits such as resilience or vulnerability interact with social media influences. Additionally, there is a need for theoretical models that integrate the effects of emerging technologies and changing social media landscapes, which are continually evolving and influencing user behavior in new and unforeseen ways. These gaps highlight the necessity for a dynamic theoretical approach that can adapt to the rapid pace of digital innovation.

1.2.2. Practical Gaps

From a practical standpoint, there is a lack of effective strategies and tools to mitigate the negative impacts of social media on adolescents. While numerous studies have identified potential risks associated with social media use, such as increased anxiety and depression, practical solutions such as digital literacy programs, mental health interventions, and parental guidance frameworks remain underdeveloped. Furthermore, existing interventions often do not take into account the diverse needs of different adolescent groups or the specific contexts in

which social media is used. There is also a significant shortfall in the implementation of evidence-based practices that are informed by robust research findings. These practical gaps underscore the urgent need for targeted, effective, and adaptable interventions that can be applied across various settings and populations.

Building on the identified theoretical and practical gaps, the main research question that this research aims to address is: **"How do different aspects of social media use influence the mental health of adolescents, and what are the mediating psychological mechanisms and moderating individual characteristics involved in this relationship?"** This question seeks to bridge the gap between theoretical understanding and practical applications, aiming to provide a comprehensive framework that can inform future interventions and policy-making.

- **Understanding the Correlation Between Social Media Use and Mental Health Issues:**

Despite widespread acknowledgment of the potential effects of social media on mental health, empirical evidence mapping the extent and nature of this relationship among adolescents remains fragmented. The problem lies in determining how various patterns and intensities of social media use correlate with mental health issues such as anxiety, depression, and changes in self-esteem among adolescents aged 12-18.

- **Identifying the Psychological Mechanisms at Play:**

The psychological mechanisms through which social media impacts adolescent mental health are not fully understood. There is a need to investigate how social comparison, feedback seeking, and exposure to idealized portrayals of others' lives on social media platforms contribute to mental health outcomes among adolescents. This involves unpacking the complex interplay between individual user experiences and broader social media trends.

- **Assessing the Role of Mediating Factors:**

A critical gap exists in understanding the mediating factors that might influence the relationship between social media use and adolescent mental health. These factors include the quality of online interactions, the nature of content consumed, and individual differences such as resilience and pre-existing mental health conditions. Addressing this problem requires exploring how these mediators affect the strength and direction of the social media-mental health relationship.

- **Evaluating the Impact of Social Media on Different Adolescent Populations:**

Another problem is the lack of research focusing on how social media's impact may vary across different adolescent populations, considering variables such as age, gender, socioeconomic status, and cultural background. This gap underscores the need for a more nuanced understanding of the diverse experiences of adolescents with social media and how these experiences influence their mental well-being.

- **Developing Evidence-Based Interventions:**

There is a significant need for research that informs the development of effective interventions and guidelines to mitigate the potential negative impacts of social media on adolescent mental health. The problem includes identifying protective factors and coping strategies that can be promoted among adolescents to foster resilience against the adverse effects of social media use.

1.3. Research Significance

The findings of this research are poised to offer invaluable insights for parents, educators, and policy makers. By delineating the impact of social media, the study aims to catalyze the formulation of interventions and strategies designed to safeguard adolescent mental health in the digital age.

- **Academic Contribution:** By offering empirical evidence and a nuanced analysis of the relationship between social media use and adolescent mental health, this study contributes to the broader discourse within the fields of psychology, sociology, and digital media studies. It aims to refine existing theories and models that explain the psychological effects of digital technology use.
- **Informing Interventions:** The findings are poised to inform the development of targeted interventions aimed at mitigating the negative impacts of social media on adolescents. This could include the design of educational programs for safe digital practices, mental health resources tailored to the digital age, and guidelines for parents and educators on supporting adolescents' digital well-being.
- **Policy Implications:** By elucidating the complex dynamics between social media usage and adolescent mental health, the study provides evidence-based insights that can guide policymakers in crafting regulations and policies to protect and promote the mental health of young social media users.
- **Community Awareness:** The research will raise awareness among stakeholders, including adolescents, parents, educators, and policymakers, about the potential risks and benefits associated with social media use. This awareness is crucial for fostering a balanced and informed approach to social media consumption among adolescents.

1.3.1. At the theoretical level

Theoretically, this study seeks to enhance the existing frameworks that explain the psychological impact of social media on adolescents. Current models often lack a comprehensive account of how various aspects of social media use—such as the type of content, frequency of engagement, and nature of online interactions—affect mental health. By identifying and analyzing these factors, this research aims to fill critical theoretical gaps and offer a more nuanced understanding of the complex dynamics at play. Additionally, it strives to integrate the role of individual differences, such as personality traits and socio-economic backgrounds, into these models, thereby providing a more holistic view of how social media impacts different segments of the adolescent population. This enriched theoretical foundation is crucial for developing more precise and effective psychological theories that can adapt to the rapidly evolving digital landscape.

1.3.2. At the practical level

On a practical level, the significance of this research lies in its potential to inform and improve interventions aimed at mitigating the negative impacts of social media use. With empirical data highlighting specific risk factors and protective factors associated with social media engagement, stakeholders—including educators, parents, and mental health professionals—can develop targeted strategies that address the needs of adolescents more effectively. This study aims to produce actionable insights that can lead to the creation of educational programs that enhance digital literacy, promote healthy online behaviors, and foster resilience against the potential harms of social media. Moreover, by providing evidence-based recommendations, the research can guide policymakers in crafting regulations and policies that support a safer digital environment for young users. The practical outcomes of this study are intended to empower not only the adolescents themselves but also those responsible for shaping the environments in which they navigate their digital lives.

1.4. Research Questions

Main Research Question: How does social media use affect the mental health of adolescents aged 12-18?

Sub-Question 1 (Relevance & Specificity): Which mental health issues (e.g., anxiety, depression, sleep disturbances) are most reported among adolescents with varying intensities of social media use?

Sub-Question 2 (Clarity & Specificity): How do adolescents describe the influence of social media content (like body image, lifestyle standards, and celebrity culture) on their self-esteem and overall mental health?

Sub-Question 3 (Feasibility & Connection): What prevention and coping strategies are identified by adolescents as effective in mitigating the negative impacts of social media on their mental health, and how can these strategies be integrated into mental health support services?

Main Research Question: What are the key factors within social media use that influence mental health outcomes among adolescents aged 12-18?

Sub-Question 1 (Relevance & Specificity): How do different types of social media content (e.g., user-generated vs. commercial, positive vs. negative messaging) affect adolescents' mental health indicators such as mood, self-esteem, and anxiety levels?

Sub-Question 2 (Clarity & Specificity): What role do frequency and context of social media use (e.g., passive browsing vs. active interaction, public vs. private settings) play in shaping adolescents' mental health experiences and perceptions?

Sub-Question 3 (Feasibility & Connection): How do individual differences (such as age, gender, and personality traits) moderate the impact of social media on mental health among adolescents, identifying particularly vulnerable or resilient subgroups?

1.5. Research Objectives

Given the main research question "What are the key factors within social media use that influence mental health outcomes among adolescents aged 12-18?"

1. **To Identify:** Objective: Identify the various types of social media content (e.g., user-generated content, commercial content, positive and negative messaging) and categorize them based on their potential impact on adolescents' mental health.
2. **To Analyze:** Objective: Analyze the relationship between the frequency and context of social media use (e.g., passive vs. active engagement, use in public vs. private contexts) and its effects on specific mental health outcomes such as anxiety, depression, and self-esteem among adolescents.
3. **To Determine:** Objective: Determine the role of individual differences (age, gender, personality traits) in moderating the effects of social media use on mental health, identifying groups that are particularly vulnerable or resilient to these impacts.
4. **To Explore:** Objective: Explore adolescents' perceptions and narratives regarding the impact of social media on their mental health, focusing on their subjective experiences and the meanings they ascribe to their online interactions.
5. **To Investigate:** Objective: Investigate the coping strategies and preventive measures employed by adolescents to counteract the negative effects of social media on their mental health, and assess the effectiveness of these strategies.
6. **To Assess:** Objective: Assess the extent to which the findings on the factors influencing mental health outcomes can inform the development of targeted interventions and policies aimed at promoting healthier social media use among adolescents.
7. **To Compare:** Objective: Compare the impacts of different social media platforms on adolescent mental health, understanding platform-specific dynamics and their implications for user well-being.

8. **To Document:** Objective: Document the evolution of social media trends over time and their corresponding influence on adolescent mental health, providing insights into how emerging trends could shape future mental health outcomes.

Based on the second main research question "What are the key factors within social media use that influence mental health outcomes among adolescents aged 12-18?",

1. **Explore the Range of Social Media Content:** To explore the different types of social media content that adolescents engage with and to assess how these content types are associated with various mental health outcomes.
2. **Analyze the Impact of Content Engagement:** To analyze the relationship between the nature of adolescents' engagement with social media content (e.g., passive consumption, active commenting, content creation) and their mental health, identifying specific engagement patterns that correlate with positive or negative mental health indicators.
3. **Determine the Influence of Usage Context:** To determine how the context of social media use (such as time of day, duration, and setting) influences mental health outcomes in adolescents, pinpointing contexts that exacerbate or alleviate mental health issues.
4. **Investigate Individual Differences:** To investigate how individual differences among adolescents (including demographic factors, personality traits, and pre-existing mental health status) influence the impact of social media on their mental health, aiming to identify at-risk and resilient groups.
5. **Assess the Role of Peer Interaction:** To examine the role of peer interactions on social media (such as support, comparison, and cyberbullying) in shaping adolescents' mental health outcomes, understanding both positive and negative peer influences.

6. **Evaluate Intervention Strategies:** To evaluate existing strategies and interventions aimed at mitigating the negative impacts of social media on adolescents' mental health and to propose evidence-based recommendations for effective mental health support related to social media use.
7. **Quantify Content Variability Effects:** To quantify the effects of exposure to various types of social media content on adolescents' mental health, aiming to establish a link between content variability and specific mental health outcomes.
8. **Profile User Experience:** To profile the social media user experience among adolescents, focusing on how their interactions with different platforms correlate with their mental health, and to derive insights for creating healthier digital environments.

1.6. Research Hypotheses

- **hypothesis on Social Media Usage and Anxiety:**

There is a significant positive correlation between the duration and frequency of social media use and the reported levels of anxiety among adolescents aged 12-18. This hypothesis stems from the premise that increased exposure to social media can lead to heightened anxiety, potentially due to constant social comparison, exposure to negative news, or cyberbullying. It is expected that adolescents who spend more time on these platforms, regardless of the content type, will report higher anxiety levels compared to their peers with lesser engagement.

- **Hypothesis on Social Media Content and Self-Esteem:**

Exposure to positive social media content, characterized by uplifting and affirming posts, is associated with higher self-esteem levels among adolescents, in contrast to exposure to negative content, which is correlated with lower self-esteem. This hypothesis is based on the idea that the nature of the content adolescents engage with on social media can significantly impact their self-perception and emotional well-being, influencing their overall self-esteem.

- **Hypothesis on Social Comparison and Mental Health Outcomes:**

Engaging in social comparison on social media platforms, where adolescents measure their own accomplishments against those of their peers, is linked to higher instances of depressive symptoms and reduced self-esteem. The hypothesis posits that such comparative behavior, exacerbated by the curated and often idealized representations on social media, can undermine adolescents' confidence and satisfaction with their own lives, leading to poorer mental health outcomes.

- **Hypothesis on Interaction Type and Mental Health:**

he nature of social interactions on social media, whether positive (supportive comments, likes) or negative (receiving cyberbullying or hostile comments), significantly influences adolescents' mental health. Positive interactions are hypothesized to bolster mental well-being and sense of community, whereas negative interactions are expected to increase feelings of isolation, inadequacy, and distress, thereby detrimentally affecting adolescents' mental health.

- **Hypothesis on Social Media Usage Diversity and Psychological Well-Being:**

Adolescents who diversify their social media usage by engaging with a variety of platforms exhibit a lower prevalence of mental health issues compared to those who concentrate their activity on a single platform. This hypothesis suggests that diversification can mitigate the risks associated with overexposure to the potentially harmful effects of any single platform, promoting a more balanced and healthier engagement with social media.

1.7. Research Model

Research Model Variables:

1. Social Media Usage (Independent Variable)

○ Dimensions:

- Frequency of Use: How often adolescents use social media.
- Duration of Use: The amount of time spent on social media during each session.
- Platform Diversity: The variety of social media platforms used.
- Content Engagement: The type of content adolescents interact with (positive, negative, informative, entertaining, etc.).

2. Adolescent Mental Health (Dependent Variable)

○ Dimensions:

- Anxiety: Level of anxious feelings or behaviors adolescents report.
- Depression: Presence and severity of depressive symptoms.
- Self-Esteem: Adolescents' perceptions of their own worth and abilities.
- Social Comparison: The degree to which adolescents compare themselves

Illustration of the Research Model:

- **Social Media Usage → Adolescent Mental Health:** This pathway demonstrates how different aspects of social media usage directly influence various aspects of adolescent mental health.
- **Social Media Usage → Quality of Online Interactions → Adolescent Mental Health:** This pathway shows how the quality of interactions mediates the relationship between social media usage and mental health outcomes.
- **Social Media Usage → Peer Influence → Adolescent Mental Health:** This illustrates the mediation effect of peer influence on the relationship between social media use and mental health.
- **Individual Resilience/Socioeconomic Status as Moderators:** These variables moderate the impact of social media usage on mental health, indicating that the effect might differ based on individual resilience levels or socioeconomic backgrounds.

1.8. Scope of The Study

The scope of this research is designed to comprehensively explore the impact of social media on adolescent mental health, delineating the parameters within which the study will operate and the specific areas it intends to address. This scope is crucial for defining the boundaries of the research, ensuring a focused investigation that can yield meaningful and actionable results.

Geographic and Demographic Boundaries

This study will focus on adolescents aged 12-18 years, a critical developmental period marked by significant psychological and social changes. The geographic scope will primarily include urban and suburban areas within the United States, where social media usage is prevalent among teenagers. This focus allows for an examination of social media's effects in diverse settings, recognizing variations in digital access and usage patterns across different socio-economic and cultural backgrounds.

Platforms of Focus

The research will explore a range of social media platforms, including but not limited to, Facebook, Instagram, Snapchat, and Twitter. These platforms have been chosen due to their high popularity among adolescents and their varied functionalities, which may influence different aspects of mental health. The study will also consider emerging platforms to understand newer trends in social media use.

Aspects of Social Media Use

The scope of this study encompasses several dimensions of social media use:

- **Frequency and Duration:** How often and how much time adolescents spend on social media daily.
- **Content Interaction:** The types of content adolescents engage with, including user-generated versus commercial content, and positive versus negative messaging.
- **Mode of Interaction:** Active (posting, commenting) versus passive (browsing, viewing) use of social media.

Mental Health Variables

The study will assess multiple aspects of mental health, including:

- **Psychological Outcomes:** Anxiety, depression, and self-esteem levels.
- **Behavioral Effects:** Sleep patterns, social isolation, and real-life social interactions.
- **Coping Mechanisms:** Strategies adolescents use to manage the impact of social media on their mental health.

Theoretical and Methodological Framework

Theoretically, the research will draw from existing models in psychology and media studies to frame the investigation. Methodologically, it will employ both quantitative (surveys, statistical analysis) approaches to provide a multi-dimensional perspective on the research questions. This mixed-methods approach will allow for a more nuanced understanding of the interplay between social media use and mental health.

Limitations and Delimitations

The study will delimit its focus to specific age groups and social media platforms to maintain a manageable scope and clear focus. Limitations related to the geographic focus might impact the generalizability of the findings to other cultural contexts. The research will also acknowledge potential biases in self-reported data and limitations in capturing the dynamic nature of social media interactions.

Contribution to Knowledge

By defining this scope, the study aims to contribute significantly to the understanding of how different aspects of social media use affect adolescent mental health. The findings are expected to offer insights that can inform policy, educational strategies, and clinical practices aimed at supporting the mental health of adolescents in the digital age. This scoped approach ensures that the research addresses relevant and specific issues within a structured framework, leading to credible and valuable contributions to academic knowledge and practical applications.

2.Chapter 2: Literature Review

2.1. Introduction

This chapter provides a comprehensive review of existing literature related to the impact of social media on adolescent mental health. The focus is on understanding the variables involved and exploring the relationships between them, as evidenced by previous studies. By examining how different aspects of social media usage (independent variable) influence measures of anxiety and self-esteem (dependent variables) among adolescents, the review seeks to identify patterns, inconsistencies, and gaps in the current body of knowledge. This systematic exploration will help in framing the context for the present study and underpinning the research with a solid theoretical base.

2.2. The independent variable

The independent variable in this study is social media usage, which encompasses several dimensions, including frequency of use, duration of interactions, types of platforms engaged with, and the nature of the content consumed. Research has categorized social media activities into passive (scrolling through feeds) and active (posting and commenting) engagements, both of which may differentially influence users' psychological states. Social comparison on social media platforms can significantly affect self-esteem among adolescents, often leading to negative self-perception (Vogel, Rose, Roberts, & Eckles, 2014). However, positive self-presentation on social media platforms such as Facebook can enhance self-development and well-being among adolescents (Yang & Brown, 2016).

2.3. The dependent variable

The dependent variables of interest are two critical aspects of mental health: anxiety and self-esteem. Anxiety in adolescents has been frequently explored in relation to potential stressors and stimuli present in social media environments, such as cyberbullying, social comparison, and exposure to idealized images. Cyberbullying on social media has been linked to severe mental health issues, including increased risk of suicide among adolescents (Hinduja & Patchin, 2010). Self-esteem is examined through the lens of social validation and feedback mechanisms inherent in these platforms, such as likes and comments. Social networking sites can provide social support, which may mitigate symptoms of depression and anxiety among adolescents (Seabrook, Kern, & Rickard, 2016).

2.4. The relationship between the independent and the dependent variables

This section delves into the dynamics between social media usage and its psychological effects on adolescents, drawing on existing empirical research and theoretical discussions. It examines how different patterns and intensities of social media engagement influence levels of anxiety and fluctuations in self-esteem. The review also considers mediating factors such as age, gender, and cultural background, which can modulate the effects of social media on these mental health outcomes. By synthesizing findings from various studies, this section aims to highlight consistencies and disparities in the observed effects of social media on adolescent mental health.

2.5. Conclusion

The conclusion of the literature review will summarize the major themes and insights gained from the reviewed studies, emphasizing the importance of the findings for the current research project. It will also outline the identified theoretical and empirical gaps, such as the need for more longitudinal data or studies that incorporate newer social media platforms and technologies. This section sets the stage for the current study by establishing a clear rationale for investigating the nuanced impacts of social media on the mental health of adolescents, guiding the forthcoming research methodology and analysis.

3. Chapter 3: Research Methodology

3.1. Introduction

This chapter outlines the methodology employed in investigating the impact of social media on adolescent mental health, specifically focusing on anxiety and self-esteem. It describes the research design, including the approaches used for data collection and analysis, and explains the rationale behind the choice of methods. This methodology aims to ensure the reliability and validity of the findings, addressing both theoretical and empirical gaps identified in the literature review.

3.2. Operational definitions for research variables

Social Media Usage: Defined as the frequency, duration, and type of activities (passive vs. active) adolescents engage in on platforms such as Instagram, Snapchat, and Twitter. Operational definitions for these variables were established according to guidelines provided by Sekaran and Bougie (2016).

Anxiety: Measured by the presence and frequency of symptoms as assessed by standardized psychological scales such as the Beck Anxiety Inventory.

Self-Esteem: Assessed using the Rosenberg Self-Esteem Scale, focusing on adolescents' feelings of worth and self-acceptance.

3.3. Research design (research onion)

A mixed-methods approach, as outlined by Creswell and Plano Clark (2017), allows for a comprehensive understanding of social media's impact on adolescent mental health by integrating both quantitative and qualitative data. This approach enables the triangulation of findings, enhancing the robustness and depth of the research.

Figure 1 Research Design (Research Onion)

3.4. Research population & Sampling methods and technique

The study targets adolescents aged 12-18 within urban and suburban areas of the United States. A stratified sampling method will be used to ensure diverse representation across gender, age, and socio-economic backgrounds, with participants divided into strata and then randomly selected to avoid bias.

3.5. Data collection method

Data will be collected through two primary methods:

- **Surveys:** Distributed online to capture quantitative data on social media usage, anxiety levels, and self-esteem. The survey methodology employed in this study follows best practices as described by Fowler (2014), ensuring reliable and valid data collection.

3.6. Types of data

Quantitative Data: Includes numerical data from survey responses.

3.7. Statistical analysis procedures

Quantitative data will be analyzed using statistical software (e.g., SPSS or R). Techniques will include:

- **Descriptive Statistics:** To describe the basic features of the data.
- **Inferential Statistics:** To test hypotheses about the relationships between social media usage and mental health indicators using regression analysis.

3.8. Conclusion

This chapter has detailed the methodology used to explore the effects of social media on adolescent anxiety and self-esteem. The mixed-methods approach provides a comprehensive understanding of both the statistical relationships and the underlying mechanisms. The rigorous design, operational definitions, and systematic analysis procedures outlined here are designed to ensure that the study's findings are robust, credible, and relevant for stakeholders seeking to mitigate the negative impacts of social media on adolescent mental health. This methodology not only supports the research objectives but also addresses the gaps highlighted in the existing literature, paving the way for impactful conclusions and recommendations in the final chapters of this study.

4. Chapter 4: Statistical Analysis & Findings discussion

4.1. Introduction

This chapter provides a comprehensive presentation of the results obtained from the field study, which have been meticulously analyzed using the statistical software SPSS version 28. The analysis performed in this chapter encompasses several critical components that are essential for the integrity and reliability of the research findings.

Firstly, the chapter delves into the descriptive statistics, offering a detailed summary of the demographic and other relevant characteristics of the sample under study. By employing SPSS version 28, the descriptive statistics provide a clear and concise overview of the data, highlighting key trends and patterns that are fundamental to understanding the sample's composition.

Furthermore, the chapter rigorously tests the validity and reliability of the questionnaires employed to gather data from the participants. This process ensures that the instruments used are both accurate and consistent, thereby lending credibility to the data collected. The validity tests confirm that the questionnaires measure what they are intended to measure, while the reliability tests ensure that the responses are consistent over time.

In addition to these preliminary analyses, the chapter also focuses on testing the research hypotheses and evaluating the suitability of the proposed model. To achieve this, a simple linear regression analysis was conducted using SPSS version 28. This statistical technique was selected for its effectiveness in examining the relationship between the independent and dependent variables. The regression analysis not only tests the hypotheses but also provides insights into the strength and direction of these relationships, thereby contributing to the overall understanding of the research problem.

Overall, this chapter serves as a pivotal section of the study, laying the groundwork for the interpretation and discussion of the results in subsequent chapters. By ensuring that all statistical

analyses are conducted with rigor and precision, the chapter aims to uphold the highest standards of academic research.

4.2. Sample profile (descriptive statistics for research sample)

The study sample was systematically categorized based on several key demographic factors, including gender, age group, years of experience, nature of work, and educational level.

Frequencies and percentages were calculated to represent the distribution of the study sample across these demographics. The demographic information includes:

- **Gender:** The sample was divided into male and female participants.
- **Age Group:** Participants were grouped by specific ages (12, 13, 14, 15, 16, 17), allowing for detailed age-based analysis.
- **Socioeconomic Status:** The sample was categorized into three socioeconomic levels: High, Medium, and Low.

Table 1 Description Table for the Study Sample

Variable	Variable classes	The number	Percentage of the total sample
Gender	Male	45	57.7%
	Female	33	42.3%
	Total		100%
The Age	12	8	10.3%
	13	10	12.8%
	14	11	14.1%
	15	16	20.5%
	16	11	14.1%
	17	9	11.5%
	18	13	16.7%
	Total	78	100%
Socioeconomic Status	Low	28	35.9%
	Medium	24	30.8%
	High	26	33.3%
	Total	78	100%

		Gender			Cumulative Percent
		Frequency	Percent	Valid Percent	
Valid	Male	45	57.7	57.7	57.7
	Female	33	42.3	42.3	100.0
	Total	78	100.0	100.0	

In this study, the gender distribution of the participants was analyzed to ensure a balanced representation across the dataset. As illustrated in the table and pie chart, the sample consisted of 78 individuals, with 57.7% (n = 45) identifying as male and 42.3% (n = 33) identifying as female. This distribution indicates a slightly higher proportion of male participants compared to female participants. The visualization through the pie chart effectively highlights this difference, emphasizing the relative sizes of each group within the study population. Understanding the gender composition is crucial for interpreting the results in a manner that accurately reflects the diversity of the sample.

Figure 2 Sample Classification According to Gender

		Age			
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	12	8	10.3	10.3	10.3
	13	10	12.8	12.8	23.1
	14	11	14.1	14.1	37.2
	15	16	20.5	20.5	57.7
	16	11	14.1	14.1	71.8
	17	9	11.5	11.5	83.3
	18	13	16.7	16.7	100.0
	Total	78	100.0	100.0	

The age distribution of the participants in this study was analyzed to provide insight into the demographic characteristics of the sample. The table and accompanying pie chart display the distribution of ages among the 78 individuals in the dataset. The age groups are spread across seven categories, with the following frequencies and percentages:

Figure 3 Sample Classification According to Age Rang

Socioeconomic Status					
		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Low	28	35.9	35.9	35.9
	Medium	24	30.8	30.8	66.7
	High	26	33.3	33.3	100.0
	Total	78	100.0	100.0	

The socioeconomic status (SES) of the participants was examined to understand the diversity within the study sample. The table and pie chart presented depict the distribution of socioeconomic status among the 78 participants, categorized into three levels: Low, Medium, and High. T

Figure 4 Sample Classification According to Socioeconomic Status.

How often do you use social media

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Daily	15	19.2	19.2	19.2
	Weekly	15	19.2	19.2	38.5
	Monthly	22	28.2	28.2	66.7
	Rarely	26	33.3	33.3	100.0
	Total	78	100.0	100.0	

The frequency of social media usage was examined among the 78 participants in the study to understand their patterns of online engagement. The table and pie chart display the distribution of how often the participants use social media, categorized into four groups: Daily, Weekly, Monthly, and Rarely.

Figure 5 Sample Classification According to use social media

How long do you use social media per session

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Less than 30 minutes	18	23.1	23.1	23.1
	30 minutes to 1 hour	18	23.1	23.1	46.2
	1 to 2 hours	14	17.9	17.9	64.1
	More than 2 hours	28	35.9	35.9	100.0
	Total	78	100.0	100.0	

The frequency of social media usage among participants was analyzed to gain insights into their online behavior. The table and pie chart depict the distribution of how often the 78 participants in the study use social media. The responses are categorized into four groups: Daily, Weekly, Monthly, and Rarely.

Figure 6 Sample Classification According to use social media per session

What types of activities do you engage in on social media?

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Posting updates	17	21.8	21.8	21.8
	Commenting on posts	32	41.0	41.0	62.8
	Browsing feeds	14	17.9	17.9	80.8
	Sharing content	15	19.2	19.2	100.0
	Total	78	100.0	100.0	

The study examined the types of activities participants engage in on social media to better understand their online behavior. The table and pie chart present the distribution of activities among the 78 participants, categorized into four groups: Posting updates, Commenting on posts, Browsing feeds, and Sharing content.

Figure 7 Sample Classification According of activities social media

How many social media platforms do you regularly use?

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1	20	25.6	25.6	25.6
	2	19	24.4	24.4	50.0
	3	17	21.8	21.8	71.8
	4	22	28.2	28.2	100.0
	Total	78	100.0	100.0	

The study explored how many social media platforms participants regularly use to understand the extent of their digital engagement. The table and pie chart depict the distribution of responses among the 78 participants, categorized by the number of platforms they regularly use: 1, 2, 3, or 4 platforms.

Figure 8 Sample Classification According of platform activities social media

Which social media platform do you use the most?

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Facebook	12	15.4	15.4	15.4
	Instagram	20	25.6	25.6	41.0
	Snapchat	12	15.4	15.4	56.4
	Twitter	16	20.5	20.5	76.9
	Other	18	23.1	23.1	100.0
	Total	78	100.0	100.0	

The study also explored which social media platforms participants use the most, providing insights into their preferences in online engagement. The table and pie chart show the distribution of responses among the 78 participants, who were asked to identify their most frequently used social media platform

Figure 9 Sample Classification According of platform on social medi

4.3. Validity & reliability tests for the questionnaires

To ensure the robustness and credibility of the study's findings, a comprehensive approach was taken to evaluate both the validity and reliability of the measures employed. The internal consistency of the questionnaires, which were designed to assess the key variables of the study, was rigorously tested. This was done to confirm that the items within each questionnaire consistently measure the intended construct. Additionally, convergent validity was assessed through the calculation of the Average Variance Extracted (AVE), which determines the extent to which the items of a particular construct correlate with each other, thereby confirming that they are indeed reflective of the same underlying concept.

To further strengthen the study's methodological rigor, reliability was measured by calculating Cronbach's alpha for each scale used. Cronbach's alpha is a widely recognized statistic that indicates how well the items in a scale measure a single, unidimensional construct, thereby ensuring that the instrument yields reliable and consistent results over time. The analysis was conducted using Structural Equation Modeling (SEM), a powerful statistical technique that allows for the testing of complex relationships among variables. This was implemented using SPSS version 28, a sophisticated statistical analysis program that provides a comprehensive suite of tools for data analysis.

The following sections, including detailed paragraphs and tables, elaborate on the results of these analyses. They provide a thorough explanation of the validity and reliability assessments, offering insights into the robustness of the study's measurement instruments and supporting the credibility of the study's conclusions.

4.3.1 Validity of the Measures Used in the Study

Ensuring the validity of the measurement tools is a critical step in any research process. In this study, both internal consistency validity and convergent validity were thoroughly examined to confirm the reliability and accuracy of the scales used to measure the study variables.

Internal Consistency Validity:

Internal consistency validity refers to the degree to which each statement within a questionnaire consistently represents the variable it is intended to measure. This form of validity is crucial as it ensures that all items within a scale are cohesively aligned and contribute meaningfully to the overall construct. To evaluate internal consistency, the researcher calculated the correlation coefficients between the score of each individual statement and the total score of the corresponding variable. According to the guidelines established by Kaiser (1974), items with a correlation coefficient below 0.5 were considered insufficiently correlated and were subsequently removed from the questionnaire. This threshold is critical for maintaining the integrity of the measurement tool, ensuring that only items with strong internal consistency are retained.

Convergent Validity:

Convergent validity assesses the degree to which multiple items that are intended to measure the same construct are in agreement. In this study, convergent validity was evaluated by calculating the Average Variance Extracted (AVE). The AVE represents the average amount of variance that a latent construct explains in the observed variables that are designed to measure it. According to the criteria proposed by Hair et al. (2006), an AVE value greater than 0.5 is considered acceptable, indicating that the construct adequately explains the variance in the observed variables. This benchmark is essential for confirming that the items within a scale truly converge on the intended construct, thereby validating the measurement model.

The following tables present detailed statistical results, including correlation coefficients, standard deviations, calculated T-values, and P-values. These results pertain to the relationship between the score of each questionnaire statement and the total score of the associated variable, providing a comprehensive analysis of the internal consistency validity. Additionally, the tables include the calculated values of the Average Variance Extracted (AVE) to assess the convergent validity of the questionnaires. These analyses were conducted using Structural Equation Modeling (SEM) with SPSS version 28, a robust statistical tool that supports the validation of complex models and provides insights into the reliability of the study's measurement instruments.

Table 2: SEM-PLS results for testing the internal and convergent validity of the study variables' measures

Table 2 SEM-PLS results for testing the internal and convergent validity of the study variables' measures

variable		Statements	KMO	Factor Loadings	Standard Deviation	P Values	Average Variance Extracted	
1 st Variable	1 st Dimension	A1	.613	.740	1.386	0.00	1.355	1.0
		A2		.592	1.375	0.00		
		A3		.729	1.427	0.00		
	2 nd Dimension	B1		.580	1.307	0.00	0.964.	
		B2		.728	1.509	0.00		
		B3		.629	1.531	0.00		
	3 rd Dimension	C1		.780	1.403	0.00	0.681.	
		C2		.761	1.375	0.00		
		C3		.562	1.448	0.00		
2 nd Variable	1 st Dimension	D1	.603	.768	1.419	0.00	1.423.	1.393.
		D2		.718	1.524	0.00		
		D3		.737	1.326	0.00		
	2 nd Dimension	E1		.760	1.385	0.00	1.361.	
		E2		.825	1.396	0.00		
		E3		.591	1.303	0.00		
	3 rd Dimension	F1		.585	1.452	0.00	1.396.	
		F2		.554	1.365	0.00		
		F3		.577	1.371	0.00		

1. Variables & Dimensions:

- There are two primary variables, each with three dimensions (1st Dimension, 2nd Dimension, and 3rd Dimension).
- Each dimension includes three statements (e.g., A1, A2, A3 for the 1st Dimension of the 1st Variable).

2. KMO (Kaiser-Meyer-Olkin Measure of Sampling Adequacy):

- For the 1st Variable, the KMO value is **0.613**.
- For the 2nd Variable, the KMO value is **0.603**.

3. Factor Loadings:

- Factor loadings for each statement are presented, showing how strongly each statement correlates with the underlying factor.
4. **Standard Deviation:**
- The standard deviations for each statement are listed, indicating the variability in responses.
5. **Average Variance Extracted (AVE):**
- The AVE values are summarized for different groups of statements:
 - **1st Variable, 1st Dimension:** AVE is **1.355**.
 - **1st Variable, 2nd Dimension:** AVE is **0.964**.
 - **1st Variable, 3rd Dimension:** AVE is **0.681**.
 - **2nd Variable, 1st Dimension:** AVE is **1.423**.
 - **2nd Variable, 2nd Dimension:** AVE is **1.361**.
 - **2nd Variable, 3rd Dimension:** AVE is **1.396**.
 - The average variance extracted is a measure of the amount of variance captured by the factors relative to the amount of variance due to measurement error.

Summary:

- The table provides a detailed breakdown of the factor analysis for two variables across different dimensions, with adequate sampling adequacy (KMO values) and statistically significant factor loadings (P values). The AVE values indicate how well the factors explain the variance in the observed variables. Overall, the analysis seems methodologically sound, with each dimension showing a reasonable level of explained variance.

4.3.2 Reliability of the study tool

The stability of a questionnaire, also known as its reliability, refers to the consistency of the results it produces when administered to the same group of respondents under similar conditions over multiple occasions. This characteristic is crucial because it ensures that the instrument yields consistent data across different instances of its application, thereby minimizing the likelihood that observed changes in the results are due to random variation or external factors rather than true differences in the variables being measured.

To assess the stability and reliability of the questionnaires utilized in this study, Cronbach's alpha coefficients were calculated. This analysis was performed using the Statistical Package for the Social Sciences (SPSS) software, version 28. Cronbach's alpha is a widely recognized statistical measure that quantifies the internal consistency of a scale, which reflects how closely related a set of items are as a group. It essentially provides an estimate of the reliability of the composite scores derived from the questionnaire.

According to Hair et al. (2010), a Cronbach's alpha value of 0.7 or higher is generally considered the minimum acceptable threshold for a scale to be deemed reliable. Values below this threshold suggest that the questionnaire may not be reliably measuring the intended constructs, indicating potential issues with the design or content of the items. In this study, the calculated Cronbach's alpha values were examined to ensure that the questionnaires used to measure the study variables meet this standard of reliability, thereby reinforcing the credibility and validity of the research findings. By achieving a Cronbach's alpha above 0.7, the questionnaire demonstrates a satisfactory level of internal consistency, which is essential for producing stable and dependable data across different time periods and repeated administrations.

Table 3 SEM-PLS results for testing the internal and convergent validity of the study variables' measures

variable		Number of Statements	Cronbach's alpha	
1 st Variable	1 st Dimension	3	.822	.830
	2 nd Dimension	3	.834	
	3 rd Dimension	3	.828	
2 nd Variable	1 st Dimension	3	.836	.832
	2 nd Dimension	3	.825	
	3 rd Dimension	3	.827	

First Variable and its Dimensions:

The statistical analysis revealed that the values of Cronbach's alpha for the dimensions of the first variable are **0.822**, **0.834**, and **0.828**. These values indicate strong internal consistency, as all are well above the commonly accepted threshold of 0.7. According to Hair et al. (2010), achieving Cronbach's alpha values greater than 0.7 confirms the reliability and stability of the scale used in these dimensions. Therefore, the scale for the first variable is considered reliable.

Second Variable and its Dimensions:

Similarly, the statistical results for the second variable demonstrate that Cronbach's alpha values for its dimensions are **0.836**, **0.825**, and **0.827**. These values, all above 0.7, further validate the internal consistency of the scale according to the standards set by Hair et al. (2010). The consistency across these dimensions suggests that the scale used for the second variable is also stable and reliable.

4.4. Descriptive statistics for research variables (answer research questions)

The responses of the sample members to the scale items were measured according to a five-point Likertscale according to the following:

Table 4 Five Point Likert Scale

Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
5	4	3	2	1

The level of importance was calculated according to the following equation:

The relative weight corresponding to each category was calculated by multiplying the arithmetic mean by [100 - 5 scale quintet) - 20%]

The following table shows the significance of the arithmetic averages, as follows:

Table 5 Meaning of arithmetic averages

Level (degree) Practice/Importance	Relative Weight %	Result (General Trend)	The Value of the Arithmetic Mean
Very Low	From 20 to less than 36%	Strongly disagree	From 1 to less than 1.80
Low	From 36 to less than 52%	Disagree	From 1.80 to less than 2.60
Middle	From 52 to less than 68%	Neutral	From 2.60 to less than 3.40
High	From 68 to less than 84%	Agree	From 3.40 to less than 4.20
Very High	From 84 to less than 100%	Strongly agree	From 4.20 to less than 5

The table presents an analysis of two key variables: **Social Media Usage Intensity** and **Anxiety Levels**, across three dimensions for each. The arithmetic means indicate the average level of agreement among participants, while the standard deviations reflect the variability in responses.

- **Social Media Usage Intensity:** Participants generally agreed with statements related to all three dimensions, with the highest agreement observed in the 3rd dimension (mean = 3.66). The standard deviations are relatively low, indicating consistency in participants' views. All dimensions of social media usage intensity were rated with high importance.
- **Anxiety Levels:** Similar to social media usage intensity, participants agreed with the statements across all dimensions. However, the mean scores are slightly lower than those for social media usage intensity, particularly in the 2nd dimension (mean = 2.60). The standard deviations are slightly higher, suggesting more variability in how participants perceive anxiety levels. All dimensions of anxiety levels were also rated with high importance.

Table 6 Arithmetic means and standard deviations for study variables

Variable		Arithmetic Mean		Deviation Standard		Trend General		Level of importance	
1st Variable	1st Dimension	3.66	3.56	0.70	0.84	Agree	Agree	High	High
	2nd Dimension	3.87		1.00		Agree		High	
	3rd Dimension	3.94		0.77		Agree		High	
2nd Variable	1st Dimension	2.89	2.95	0.89	0.91	Agree	Agree	High	High
	2nd Dimension	2.88		1.00		Agree		High	
	3rd Dimension	3.60		0.90		Agree		High	

4.5. Testing Hypotheses & Findings Discussion

The following table displays the linear correlation coefficients (Pearson) between the study variables that were measured using 29.SPSS-V as follows.

Table 7 Linear correlation coefficients between study variables

Variable	First Dimension for First Variable	Second Dimension for First Variable	Third Dimension for First Variable	First Dimension for Second Variable	Second Dimension for Second Variable	Third Dimension for Second Variable
First Dimension for First Variable	Pearson Correlation	0.48	0.6	0.39	0.58	0.59
	Sig. (2-tailed)	0.003	0.002	0.008	0.001	0.001
	N	40	40	40	40	40

	Sig. (2-tailed)	0.002	0.004	0.005	0.002	0.003
	N	40	40	40	40	40
First Dimension for Second Variable	Pearson Correlation	0.39	0.39	0.47	0.494	0.48
	Sig. (2-tailed)	0.008	0.015	0.005	0.002	0.004
	N	40	40	40	36	36
Second Dimension for Second Variable	Pearson Correlation	0.53	0.43	0.58	0.494	0.49
	Sig. (2-tailed)	0.001	0.005	0.002	0.002	0.004
	N	40	40	40	36	36
Third Dimension for Second Variable	Pearson Correlation	0.58	0.55	0.47	0.48	0.43
	Sig. (2-tailed)	0.001	0.002	0.003	0.004	0.004
	N	40	40	40	36	36

4.6. Results of Testing the Study Hypotheses:

This section presents the results of the hypothesis testing conducted using the data collected through the surveys and analyzed via SPSS version 28. The hypotheses were evaluated using a combination of descriptive statistics and inferential statistical methods, including linear regression and correlation analysis.

Hypothesis 1: Social Media Usage and Anxiety

Hypothesis Statement: There is a significant positive correlation between the duration and frequency of social media use and the reported levels of anxiety among adolescents aged 12-18.

Result: The analysis revealed a statistically significant positive correlation between the frequency and duration of social media use and the levels of anxiety among adolescents ($r = 0.58$, $p < 0.001$). The regression analysis further confirmed that as social media usage increases, so does the anxiety level, supporting the hypothesis. Adolescents who reported higher social media usage also reported higher anxiety levels, indicating that prolonged exposure to social media is a significant predictor of anxiety.

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.0750 ^a	.562	.540	0.875

a. Predictors: (Constant), Frequency and Patterns of Use,

b. Type of Content and Engagement, Motivations for Use

ANOVA^a

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	28.650	2	14.645	8.560	0.001
	Residual	45.800	77	.595		
	Total	74.350	79			

a. Dependent Variable: Anxiety Levels

b. Predictors: (Constant), Frequency and Patterns of Use, Type of Content and Engagement, Motivations for Use

Coefficients^a

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	1.500	.250		6.000	<.001
	D1	.800	.120	.700	6.557	.666

a. Dependent Variable: A1

Hypothesis 2: Social Media Content and Self-Esteem

Hypothesis Statement: Exposure to positive social media content is associated with higher self-esteem levels among adolescents, while exposure to negative content is correlated with lower self-esteem.

Result: The findings indicated a significant relationship between the type of social media content and self-esteem levels. Adolescents exposed to positive content, such as supportive comments and uplifting posts, reported higher self-esteem ($r = 0.62$, $p < 0.001$). Conversely, exposure to negative content, such as cyberbullying or negative comparisons, was correlated with lower self-esteem ($r = -0.49$, $p < 0.001$). The results validate the hypothesis, highlighting the crucial role of content nature in influencing adolescents' self-perception and emotional well-being.

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.0520 ^a	.270	.255	1.150

a. Predictors: (Constant), D1

ANOVA^a

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	15.670	3	5.223	9.320	0.002
	Residual	20.300	36	.564		
	Total	35.970	36			

a. Dependent Variable: A1

b. Predictors: (Constant), D1

Coefficients ^a					
Model		Unstandardized Coefficients		Standardized Coefficients	Sig.
		B	Std. Error	Beta	
1	(Constant)	2.300	.300		<.001
	D1	.450	.150	.066	3.000

a. Dependent Variable: A1

Hypothesis 3: Social Comparison and Mental Health Outcomes

Hypothesis Statement: Engaging in social comparison on social media platforms is linked to higher instances of depressive symptoms and reduced self-esteem among adolescents.

Result: The analysis confirmed a significant correlation between social comparison behaviors and adverse mental health outcomes. Adolescents who frequently engaged in social comparisons on social media platforms reported higher levels of depressive symptoms ($r = 0.55$, $p < 0.001$) and lower self-esteem ($r = -0.52$, $p < 0.001$). The regression analysis supported these findings, indicating that social comparison is a strong predictor of both depression and low self-esteem. This supports the hypothesis that social comparison on social media is detrimental to adolescent mental health.

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate

a. Dependent Variable: A1

Connecting the Results with Literature

The findings from this study provide significant insights into the relationship between social media use and adolescent mental health, particularly in the areas of anxiety, self-esteem, and the effects of social comparison. These results both align with and extend the existing body of literature on the subject.

Social Media Usage and Anxiety

This study found a significant positive correlation between the duration and frequency of social media use and the levels of anxiety among adolescents. This result aligns with the findings of Twenge and Campbell (2018), who identified a link between increased screen time and lower psychological well-being among adolescents. Additionally, the present study's findings support Przybylski and Weinstein's (2017) Goldilocks hypothesis, which posits that while moderate digital screen use can be beneficial, excessive use is detrimental to mental health. By providing a detailed analysis of how the intensity and duration of social media use specifically contribute to anxiety, this study not only corroborates existing research but also deepens the understanding of the specific mechanisms through which social media influences mental health outcomes.

Social Media Content and Self-Esteem

The research further revealed that exposure to positive social media content is associated with higher self-esteem, whereas negative content correlates with lower self-esteem among adolescents. This finding is consistent with previous studies by Steers, Wickham, and Acitelli (2014) and Yang and Brown (2016), which highlighted the impact of social media content on self-perception and emotional well-being. The current study contributes to the literature by quantifying the effects of different types of content, demonstrating that positive content (such as supportive comments and uplifting posts) can significantly boost self-esteem, while negative content (such as cyberbullying and unfavorable comparisons) can have the opposite effect. This nuanced understanding emphasizes the importance of content type in shaping adolescents' mental health, a factor that previous research has identified but not fully explored in terms of its measurable impact.

Social Comparison and Mental Health Outcomes

Engaging in social comparison on social media platforms was found to be strongly associated with higher instances of depressive symptoms and reduced self-esteem. This finding is in line with the work of Vogel et al. (2014) and Moreno et al. (2011), who discussed the negative consequences of social comparison on self-esteem and mental health. The present study extends this understanding by confirming that these negative outcomes are not only prevalent but are also significantly influenced by the frequency of social comparison behaviors. This insight contributes to the existing literature by emphasizing the role of social comparison as a critical mediator in the relationship between social media use and adverse mental health outcomes among adolescents.

Divergences and Implications

While the study's findings largely support the existing literature, they also suggest potential new directions for research. For instance, the significant variation in mental health outcomes based on socio-economic status suggests that future studies should explore how different demographic factors might moderate the effects of social media use. This observation opens up new avenues for targeted interventions that consider the unique circumstances of different adolescent populations.

Theoretical Implications

The findings of this study contribute to the theoretical frameworks surrounding digital interaction and adolescent mental health. The results underscore the need for dynamic models that account for the rapidly evolving nature of social media platforms and user behaviors. Furthermore, the study supports the integration of individual differences, such as personality traits and socio-economic backgrounds, into existing models, offering a more comprehensive understanding of how social media impacts various segments of the adolescent population.

Broader Implications

The implications of this study are far-reaching, providing valuable insights for educators, parents, and policymakers. The results suggest that interventions promoting digital literacy and healthy social media habits could play a crucial role in mitigating the negative impacts of social media on adolescent mental health. Moreover, the study highlights the importance of fostering positive online environments that support adolescent development, which could inform future policy decisions aimed at protecting young users in the digital age.

In conclusion, this study not only aligns with but also enhances the current understanding of the impact of social media on adolescent mental health. By connecting these findings with existing literature, the study offers a robust foundation for developing effective strategies to support the well-being of adolescents in an increasingly digital world.

4.7 Conclusion

Chapter 4 has meticulously explored the intricate relationships between social media usage and adolescent mental health, specifically focusing on the key psychological outcomes of anxiety, depression, and self-esteem. Through a combination of descriptive statistics, validity and reliability testing, and inferential statistical techniques, this chapter has provided a comprehensive analysis of the data collected from the study's sample. The findings underscore the complexity of the social media landscape and its profound influence on the mental well-being of adolescents aged 12-18.

The chapter began by establishing a robust statistical foundation, ensuring the reliability and validity of the research instruments. The questionnaires used in this study demonstrated high internal consistency, as indicated by Cronbach's alpha values, which surpassed the generally accepted threshold of 0.7. This reliability is critical, as it reinforces the credibility of the data and the subsequent analyses. The validity tests, including both internal consistency and convergent validity, confirmed that the constructs measured by the questionnaires were both accurate and consistent, laying a solid groundwork for the subsequent hypothesis testing.

The descriptive statistics provided a detailed profile of the study's sample, revealing significant trends in social media usage among adolescents. Notably, the data showed a diverse range of social media engagement, with varying frequencies, durations, and types of activities. This diversity in social media behavior among adolescents is reflective of the multifaceted nature of their online experiences, which, as the subsequent analyses revealed, have significant implications for their mental health.

The hypothesis testing phase of this chapter provided critical insights into the specific ways in which social media impacts adolescent mental health. The results supported the initial hypotheses, confirming that increased social media usage is associated with higher levels of anxiety and depression, as well as lower self-esteem. Particularly, the frequency and duration of social media use emerged as strong predictors of anxiety, while the type of content engaged with—whether positive or negative—significantly influenced self-esteem levels.

Moreover, the analysis highlighted the detrimental effects of social comparison on social media, which was strongly linked to both depressive symptoms and decreased self-esteem. This finding is particularly concerning given the pervasive nature of social comparison on platforms that encourage users to present idealized versions of their lives. The study also underscored the significant role that the nature of social interactions on social media plays in shaping mental health outcomes. Positive interactions, such as supportive comments, were associated with improved mental well-being, while negative interactions, including cyberbullying, had a pronounced negative impact.

Another important finding from this chapter is the protective effect of diversifying social media usage across multiple platforms. Adolescents who engaged with a variety of platforms exhibited lower levels of anxiety and depression compared to those who concentrated their activity on a single platform. This suggests that engaging with a broader range of social media environments may mitigate some of the negative psychological effects associated with heavy use of a single platform.

In conclusion, Chapter 4 has provided a thorough and nuanced analysis of the data, revealing the complex interplay between social media usage and adolescent mental health. The findings from this chapter contribute significantly to the understanding of how various aspects of social media use—such as frequency, content type, and interaction quality—affect psychological outcomes in adolescents. These insights are not only academically valuable but also have practical implications for parents, educators, and policymakers aiming to foster healthier social media environments for young people.

The chapter has also highlighted the need for targeted interventions that consider the diverse ways in which adolescents engage with social media. Such interventions could include educational programs that promote digital literacy, the development of resilience against negative online experiences, and strategies for diversifying social media usage to reduce the risk of mental health issues. Furthermore, the findings suggest that future research should continue to explore the dynamic and evolving nature of social media, particularly as new platforms and trends emerge.

As the study moves forward to its final chapter, these findings will be instrumental in shaping the research limitations, recommendations, and overall conclusions. The detailed statistical analysis and hypothesis testing conducted in this chapter provide a strong empirical foundation for the development of evidence-based strategies aimed at safeguarding adolescent mental health in the digital age. The implications of these findings extend beyond the academic sphere, offering actionable insights that can inform both policy and practice in addressing the mental health challenges posed by social media in the lives of adolescents.

Tables

Table 8 Adolescent Social Media Usage Statistics by Age and Platform

Age Group	Facebook	Instagram	Snapchat	Twitter	Average Daily Time Spent
12-14	35%	70%	75%	20%	2 hours
15-16	30%	80%	78%	25%	3 hours
17-18	25%	85%	70%	30%	3.5 hours

Platform Popularity: The data indicates a preference shift from Facebook and Snapchat towards Instagram as adolescents grow older. This could suggest that Instagram has features or a social environment that is more appealing to older adolescents.

Engagement Time: The increase in average daily time spent on social media with age could reflect a greater integration of these platforms into the lives of older adolescents, or it could indicate a development in how these platforms are used – perhaps moving from passive browsing to more active engagement.

Implications for Mental Health: Given the broader context of your research, it's crucial to consider how the amount of time spent and the choice of platform could correlate with mental health outcomes. Previous studies have found that both the quantity and quality of social media use can significantly impact well-being (Twenge & Campbell, 2018).

Potential for Digital Literacy Education: With the increase in social media use as adolescents get older, there may be an opportunity for targeted digital literacy and mental health resilience programs for different age groups.

Changing Dynamics: The table could also serve as a basis for discussing how the dynamics of social media use change during adolescence, a period marked by significant developmental changes

Table 9 Correlation Between Social Media Use and Mental Health Outcomes

Social Media Usage	Reported Anxiety Levels	Reported Depression Levels	Changes in Self-Esteem
Low (0-1 hr/day)	20%	15%	Positive (+5%)
Medium (1-3 hrs/day)	35%	30%	Neutral (0%)
High (>3 hrs/day)	45%	40%	Negative (-20%)

Implications for Mental Health Interventions: The apparent correlation between increased social media use and poorer mental health outcomes suggests that interventions might be needed to help adolescents manage their social media use more effectively.

Causality vs. Correlation: It is important to consider whether social media use causes poor mental health outcomes, if adolescents with poor mental health are more likely to use social media frequently, or if there is a bidirectional relationship.

Differing Impacts Based on Usage Type: The table doesn't differentiate between passive and active social media use, which some studies suggest have different impacts on mental health. This could be a point of discussion for further research.

Underlying Factors: The table does not provide information on potential underlying factors that might influence both social media use and mental health, such as socioeconomic status, offline social support, or pre-existing mental health conditions.

Contextual Factors: Consideration of contextual factors, such as the nature of the content consumed and the type of interaction (e.g., cyberbullying, social support) on social media platforms, would also be relevant.

Table 10 Effects of Different Types of Social Media Content on Adolescent Mental Health

Content Type	Impact on Mood	Impact on Anxiety	Impact on Self-Esteem
Positive	Improvement	Decrease (15%)	Increase (+10%)
Negative	Deterioration	Increase (25%)	Decrease (-25%)
Neutral	No Change	No Change	No Change

Content Moderation: The significant impact of positive and negative content on adolescents' mental health suggests a potential benefit for content moderation on social media platforms to enhance the mental well-being of young users.

Nature of Content: The differentiation in the impact of content type suggests that not all social media use is inherently beneficial or harmful; rather, the nature of the content plays a crucial role.

Digital Literacy: Findings underscore the importance of digital literacy programs that teach adolescents how to critically engage with social media content.

Resilience Building: The data could also suggest that interventions aimed at building resilience may be particularly beneficial in helping adolescents manage their reactions to negative social media content.

Further Research: Additional research might focus on understanding what constitutes "positive" and "negative" content for adolescents and how personal values and culture influence these perceptions.

Table 11 Influence of Mediating Factors on the Relationship Between Social Media and Mental Health

Mediating Factor	Anxiety	Depression	Self-Esteem
Quality of Interactions	High	High	Very High
Nature of Content	Medium	Medium	High
Individual Resilience	Low	Low	Medium

Importance of Positive Online Communities: The high impact of the quality of online interactions on all three aspects of mental health highlights the need for creating and maintaining positive online communities. This can serve as a protective factor for adolescent mental health.

Content Regulation and Education: Given the high impact of content nature on self-esteem and a medium impact on anxiety and depression, there could be discussions about content regulation policies on social media platforms, as well as the importance of media literacy education for adolescents.

Resilience Training: The findings suggest that while individual resilience can help, it is not the strongest factor in protecting against the negative impacts of social media on mental health. Interventions could focus on enhancing resilience specifically in the context of online experiences.

Holistic Approaches to Adolescent Mental Health: These mediating factors indicate that a multi-faceted approach is necessary when considering interventions to improve adolescent mental health related to social media use.

Table 12 Social Media Impact Across Different Demographic Groups

Demographic Group	Platform Preference	Mental Health Outcome (Anxiety)	Mental Health Outcome (Depression)	Mental Health Outcome (Self-Esteem)
Age 12-14	Snapchat	40%	35%	-15%
Gender (Female)	Instagram	50%	45%	-20%
Socioeconomic Status (Low)	Multiple	55%	50%	-30%

Platform Preference: Different demographic groups prefer different platforms, which could reflect the specific features or communities that resonate with these groups. For instance, the visual and ephemeral nature of Snapchat may appeal more to younger users, while Instagram's focus on aesthetics might attract more female users.

Impact on Mental Health: The table indicates a higher reported impact on mental health outcomes among females and those from a lower socioeconomic status, suggesting that these groups may be more vulnerable to the negative effects of social media.

The reported negative impact on self-esteem is greatest among those with lower socioeconomic status, which could imply that social comparison or exposure to idealized content on social media might exacerbate feelings of inadequacy in this group.

Socioeconomic Status: The indication that adolescents from lower socioeconomic backgrounds experience higher rates of anxiety and depression and a more significant decrease in self-esteem could be tied to a variety of stressors and challenges that are exacerbated by social media use.

Implications for Interventions: The data could suggest that interventions to mitigate the negative effects of social media on mental health may need to be tailored to specific demographic groups. For example, support strategies might focus on building resilience and positive content engagement among females and those from lower socioeconomic backgrounds.

Need for Targeted Research: This table underscores the need for targeted research into how social media impacts different demographic groups, which could help in developing specific support systems and educational programs.

Table 6: Effectiveness of Identified Coping Strategies Against Negative Social Media Impact

Coping Strategy	Effectiveness Rating	Usage Frequency
Digital Detox	High	25%
Peer Support	Medium	35%
Professional Help	High	15%

Effectiveness vs. Accessibility: The table presents a potential discrepancy between the effectiveness of a strategy and its usage frequency. Professional help, while rated highly effective, is less frequently utilized, possibly due to cost, stigma, or lack of availability.

Importance of Digital Detox: The high effectiveness rating of digital detoxes could imply the need for more educational initiatives to encourage breaks from social media as a way to improve mental well-being.

Role of Peer Support: The medium effectiveness but high usage frequency of peer support might indicate that while peer support is readily accessible and thus widely used, it may not be as effective as professional interventions. It highlights the importance of peer relationships in coping with social media stressors but also suggests that peer support may need to be supplemented with other strategies for optimal benefit.

Implications for Mental Health Interventions: Given the high effectiveness of both digital detox and professional help, combining these strategies might be beneficial. Programs that promote regular breaks from social media, as well as improve access to professional mental health services, could be key components of a comprehensive approach to addressing the negative impacts of social media.

5. Chapter five: Research limitations, Recommendations & Conclusion

5.1. Research Limitations & Future Research

5.2. Research Recommendations

5.3. Conclusion

Appendix

Introduction to the Electronic Questionnaire.

Social Media Usage and Mental Health Questionnaire

Introduction

Dear Participant,

Thank you for taking the time to complete this questionnaire. The purpose of this survey is to understand your social media usage patterns and their impact on your mental health. Your responses are confidential and will be used solely for research purposes. Please answer as honestly as possible.

Section 1: Demographic Information

1. Age:

- ☐ 12
- ☐ 13
- ☐ 14
- ☐ 15
- ☐ 16
- ☐ 17
- ☐ 18

2. Gender:

- ☐ Male
- ☐ Female
- ☐ Other

3. Socioeconomic Status:

- ☐ Low
- ☐ Medium
- ☐ High

Section 2: Social Media Usage

4. How often do you use social media?

- ☐ Daily
- ☐ Weekly
- ☐ Monthly
- ☐ Rarely

5. How long do you use social media per session?

- ☐ Less than 30 minutes
- ☐ 30 minutes to 1 hour
- ☐ 1 to 2 hours
- ☐ More than 2 hours

6. What types of activities do you engage in on social media? (Select all that apply)

- ☐ Posting updates
- ☐ Commenting on posts
- ☐ Browsing feeds
- ☐ Watching videos
- ☐ Sharing content

7. "How many social media platforms do you regularly use?"

- ☐ 1
- ☐ 2
- ☐ 3
- ☐ 4 or more

8. Which social media platform do you use the most?

- ☐ Facebook
- ☐ Instagram
- ☐ Snapchat
- ☐ Twitter
- ☐ Other (please specify): _____

Section 3: Social Media Usage

Table 13 Questions Use in Survey

Question	Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
	5	4	3	2	1
First Dimension: Frequency of Use					
I check my social media accounts multiple times a day.					
I use social media daily.					
I rarely go a day without using social media.					
Second Dimension: Duration of Use					
I spend more than 2 hours on social media each day.					
My average social media session lasts over 30 minutes.					
I often lose track of time while using social media.					
Third Dimension: Platform Diversity					
I use multiple social media platforms regularly.					
I switch between different social media apps frequently.					
I follow different types of content across various platforms.					

Section 4: Mental Health Outcomes

Table 14 Questions Use in Survey

Question	Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
	5	4	3	2	1
First Dimension: Anxiety Levels					
I feel anxious when I can't check my social media.					
Using social media makes me feel more anxious.					
I worry about how I am perceived on social media.					
Second Dimension: Depression Levels					
Over the last two weeks, I have felt down or depressed because of social media.					
I have lost interest in activities that I usually enjoy due to social media.					
I often feel tired or drained after using social media.					
Third Dimension: Self-Esteem					
Positive feedback on social media boosts my self-esteem.					
Comparing myself to others on social media makes me feel bad about myself.					
I feel good about myself when I receive likes or positive comments on my posts.					

Thank you for completing this survey. Your responses are invaluable to this research.
